

# The Blast Furnace: A Man-made Volcano

## THE BLAST ENGINE

The wooden blast engine and the water turbine that drove it were located in the blast house. Two five-foot diameter blowing tubs, with pistons driven by a huge walking beam, produced the blast. Air from the tubs was forced into a receiver with a weighted piston that kept the air pressure constant.

## THE HOT BLAST STOVE

Preheating the blast reduced fuel consumption. Cold air from the blast engine was piped through a row of giant cast iron tubes in a stove heated by furnace gas. Two "downcomers" carried the air to a bustle pipe that fed three nozzles, which injected it into the furnace. Water-cooled sleeves prevented the nozzles, or tuyeres, from melting in the inferno.

## What is a Blast Furnace?

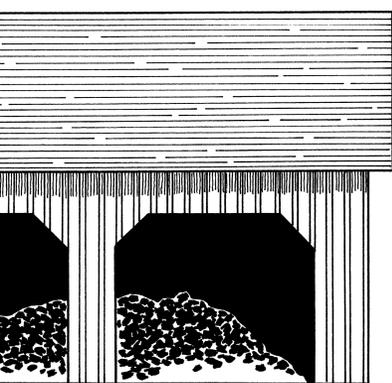

Iron, the world's most useful metal, makes up more than five percent of earth's crust and most of its core. However, elemental iron is rarely found in nature. In order to obtain pure iron, iron oxide ore must be "smelted" to remove the oxygen. The most efficient way of doing this is in a blast furnace.

Early blast furnaces were square stone towers with a vertical shaft. Ore, fuel, and limestone were fed into the top and air was blown into the bottom. As the solid materials descended in the shaft, a chemical reaction "reduced" or removed oxygen from the iron. Molten metal collected in the bottom of the furnace and slag, containing the impurities, floated on top of the heavier iron.

The conditions in a blast furnace were so similar to a volcano that some furnaces were named Etna and Vesuvius. In addition to enduring the heat and constant roar of the blast, workers were at risk from deadly gases, molten metal, and steam explosions.

**QUESTION:** What is missing from the furnace today?

**ANSWER:** All the firebrick structures are missing: smelting shaft, hot blast stove, and chimney. Firebrick was the most expensive material in the furnace. It was the only material that could resist the corrosive effects of burning gas and molten metal. Most of Oswego's firebrick was imported from England and Scotland. Because of its value, the missing brick may have been reused in the second furnace built half a mile north of here. That furnace is no longer standing.

**The Charging Terrace**  
Raw materials were stored here in sheds

**The Fillers**  
The workers who fed or "charged" the furnace with limestone, charcoal, and ore worked 12-hour shifts. They had to brave heat, deadly gases, and dust at the tunnel head.

**Charging Bridge**

**Break in Diagram**  
Indicates charging bridge was longer than shown.

**Charging the Furnace**  
Measured amounts of ore, charcoal, and limestone were fed into the furnace every 20 minutes.

**Firebrick Lining of Shaft**

**Basalt Stack**

**Tuyere Arch**

**Blast Pipe or Tuyere**

**Hearth**  
Molten iron and slag collected here.

**Chimney**

**Hot Blast Stove**

**Bosh**  
The widest part of the shaft where temperatures reached 2600° to 3000° F

**Casting Arch**

**The Founder**  
Supervised furnace operations

**Dam Stone with Taphole**

## RECIPE FOR ONE TON OF IRON

2 tons of iron ore  
1 ton of charcoal fuel  
Half a ton of limestone (a "flux" that helped to separate impurities and create slag)  
5 tons of air

## About these diagrams:

These diagrams show the furnace and blast system as they looked in 1867, but without the wooden buildings that surrounded them. The furnace was remodeled in 1878 and twelve feet were added to the top. Can you see the difference between the old and new stonework?
